The new Ruthenium catalyst for PEM electrolysis: Enabling the hyperscale with sustainable solutions

Catalyst solutions exist to enable the PEM ramp-up

Leverage Ruthenium to tackle the Iridium challenge

Ruthenium oxide shows a superior Mass Activity also if stablilyzed

Pure RuO₂ known to be unstable under operation conditions

- By adding Iridium the mixed oxide is stabilized
- With higher Ru content, the activity increases: up to 50 times higher mass activity with mixed oxides compared to pure IrO₂

The activity boost with Iridium-Ruthenium oxides enables a higher performance of the catalyst, thus less tIr/GW

- Catalysts are to-date using in average 0.4 tlr/GW
- The new Ruthenium catalyst enables up to 85% Ir reduction vs. $IrO_2 \rightarrow < 0.1 tIr/GW$

Ruthenium oxide stability confirmed—at the same level as Iridium oxide

- BOL activity of mixed oxide comparable to Ruthenium oxide
- EOL activity remains 10 % higher than Iridium oxide
- Activity loss for mixed oxides at the same level as Iridium oxide

Significant cost advantage of Iridium-Ruthenium oxide over Iridium oxide

- Reduced precious metal material cost by replacing Iridium with Ruthenium
- Reduced input power due to 10 times higher mass activity
- Further savings through optimization
